```
### Cyclistic Exercise Full Year Analysis ###
```

This analysis is for case study 1 from the Google Data Analytics Certificate (Cyclistic). It's originally based on the case study "'Sophisticated, Clear, and Polished': Divvy and Data Visualization" written by Kevin Hartman (found here:

https://artscience.blog/home/divvy-dataviz-case-study). We will be using the Divvy dataset for the case study. The purpose of this script is to consolidate downloaded Divvy data into a single dataframe and then conduct simple analysis to help answer the key question: "In what ways do members and casual riders use Divvy bikes differently?"

library(tidyverse) #helps wrangle data library(lubridate) #helps wrangle date attributes library(ggplot2) #helps visualize data getwd() #displays your working directory setwd("/Users/kevinhartman/Desktop/Divvy_Exercise/csv") #sets your working directory to simplify calls to data ... make sure to use your OWN username instead of mine;)

Compare column names each of the files

While the names don't have to be in the same order, they DO need to match perfectly before we can use a command to join them into one file

```
colnames(q3_2019)
colnames(q4_2019)
```

colnames(q2_2019)

colnames(q1 2020)

Rename columns to make them consisent with q1_2020 (as this will be the supposed going-forward table design for Divvy)

```
(q4 2019 <- rename(q4 2019
           ride id = trip id
           ,rideable type = bikeid
            ,started at = start time
            ,ended at = end time
            ,start_station_name = from_station_name
            ,start station id = from station id
            ,end station name = to station name
            ,end_station_id = to_station_id
            ,member casual = usertype))
(q3_2019 <- rename(q3 2019
           ,ride_id = trip_id
           ,rideable_type = bikeid
           ,started at = start time
            ,ended_at = end_time
            start station name = from station name
            ,start station id = from station id
            ,end_station_name = to_station_name
            ,end station id = to station id
            ,member casual = usertype))
(q2 2019 <- rename(q2 2019
           ,ride_id = "01 - Rental Details Rental ID"
            rideable type = "01 - Rental Details Bike ID"
            started at = "01 - Rental Details Local Start Time"
            ,ended_at = "01 - Rental Details Local End Time"
            start station name = "03 - Rental Start Station Name"
            start station id = "03 - Rental Start Station ID"
            ,end_station_name = "02 - Rental End Station Name"
            end station id = "02 - Rental End Station ID"
            ,member_casual = "User Type"))
# Inspect the dataframes and look for inconquencies
str(q1 2020)
str(q4_2019)
str(q3 2019)
str(q2 2019)
# Convert ride id and rideable type to character so that they can stack correctly
q4 2019 <- mutate(q4 2019, ride id = as.character(ride id)
```

Stack individual quarter's data frames into one big data frame all_trips <- bind_rows(q2_2019, q3_2019, q4_2019, q1_2020)

Remove lat, long, birthyear, and gender fields as this data was dropped beginning in 2020 all_trips <- all_trips %>%

select(-c(start_lat, start_lng, end_lat, end_lng, birthyear, gender, "01 - Rental Details Duration In Seconds Uncapped", "05 - Member Details Member Birthday Year", "Member Gender", "tripduration"))

STEP 3: CLEAN UP AND ADD DATA TO PREPARE FOR ANALYSIS

Inspect the new table that has been created colnames(all_trips) #List of column names nrow(all_trips) #How many rows are in data frame? dim(all_trips) #Dimensions of the data frame? head(all_trips) #See the first 6 rows of data frame. Also tail(qs_raw) str(all_trips) #See list of columns and data types (numeric, character, etc) summary(all_trips) #Statistical summary of data. Mainly for numerics

- # There are a few problems we will need to fix:
- # (1) In the "member_casual" column, there are two names for members ("member" and "Subscriber") and two names for casual riders ("Customer" and "casual"). We will need to consolidate that from four to two labels.
- # (2) The data can only be aggregated at the ride-level, which is too granular. We will want to add some additional columns of data -- such as day, month, year -- that provide additional opportunities to aggregate the data.
- # (3) We will want to add a calculated field for length of ride since the 2020Q1 data did not have the "tripduration" column. We will add "ride_length" to the entire dataframe for consistency.
- # (4) There are some rides where tripduration shows up as negative, including several hundred rides where Divvy took bikes out of circulation for Quality Control reasons. We will want to delete these rides.
- # In the "member_casual" column, replace "Subscriber" with "member" and "Customer" with "casual"
- # Before 2020, Divvy used different labels for these two types of riders ... we will want to make our dataframe consistent with their current nomenclature

```
contain any values from a specific level
# Begin by seeing how many observations fall under each usertype
table(all trips$member casual)
# Reassign to the desired values (we will go with the current 2020 labels)
all trips <- all trips %>%
 mutate(member casual = recode(member casual
                 ,"Subscriber" = "member"
                 ,"Customer" = "casual"))
# Check to make sure the proper number of observations were reassigned
table(all trips$member casual)
# Add columns that list the date, month, day, and year of each ride
# This will allow us to aggregate ride data for each month, day, or year ... before completing
these operations we could only aggregate at the ride level
# https://www.statmethods.net/input/dates.html more on date formats in R found at that link
all_trips$date <- as.Date(all_trips$started_at) #The default format is yyyy-mm-dd
all trips$month <- format(as.Date(all trips$date), "%m")
all trips$day <- format(as.Date(all trips$date), "%d")
all_trips$year <- format(as.Date(all_trips$date), "%Y")
all trips$day of week <- format(as.Date(all trips$date), "%A")
# Add a "ride_length" calculation to all_trips (in seconds)
# https://stat.ethz.ch/R-manual/R-devel/library/base/html/difftime.html
all trips$ride length <- difftime(all trips$ended at,all trips$started at)
# Inspect the structure of the columns
str(all_trips)
# Convert "ride length" from Factor to numeric so we can run calculations on the data
is.factor(all trips$ride length)
all trips$ride length <- as.numeric(as.character(all trips$ride length))
is.numeric(all_trips$ride_length)
# Remove "bad" data
# The dataframe includes a few hundred entries when bikes were taken out of docks and
checked for quality by Divvy or ride_length was negative
# We will create a new version of the dataframe (v2) since data is being removed
# https://www.datasciencemadesimple.com/delete-or-drop-rows-in-r-with-conditions-2/
all_trips_v2 <- all_trips[!(all_trips$start_station_name == "HQ QR" | all_trips$ride_length<0),]
```

N.B.: "Level" is a special property of a column that is retained even if a subset does not

```
# STEP 4: CONDUCT DESCRIPTIVE ANALYSIS
# Descriptive analysis on ride length (all figures in seconds)
mean(all trips v2$ride length) #straight average (total ride length / rides)
median(all trips v2$ride length) #midpoint number in the ascending array of ride lengths
max(all trips v2$ride length) #longest ride
min(all trips v2$ride length) #shortest ride
# You can condense the four lines above to one line using summary() on the specific attribute
summary(all trips v2$ride length)
# Compare members and casual users
aggregate(all trips v2$ride length ~ all trips v2$member casual, FUN = mean)
aggregate(all trips v2$ride length ~ all trips v2$member casual, FUN = median)
aggregate(all trips v2$ride length ~ all trips v2$member casual, FUN = max)
aggregate(all_trips_v2$ride_length ~ all_trips_v2$member_casual, FUN = min)
# See the average ride time by each day for members vs casual users
aggregate(all_trips_v2$ride_length ~ all_trips_v2$member_casual + all_trips_v2$day_of_week,
FUN = mean)
# Notice that the days of the week are out of order. Let's fix that.
all trips v2$day of week <- ordered(all trips v2$day of week, levels=c("Sunday", "Monday",
"Tuesday", "Wednesday", "Thursday", "Friday", "Saturday"))
# Now, let's run the average ride time by each day for members vs casual users
aggregate(all_trips_v2$ride_length ~ all_trips_v2$member_casual + all_trips_v2$day_of_week,
FUN = mean)
# analyze ridership data by type and weekday
all trips v2 %>%
 mutate(weekday = wday(started at, label = TRUE)) %>% #creates weekday field using
 group by(member casual, weekday) %>% #groups by usertype and weekday
 summarise(number of rides = n()
                                                                            #calculates
the number of rides and average duration
 average duration = mean(ride length)) %>%
                                                       # calculates the average duration
 arrange(member casual, weekday)
                                                                                  # sorts
# Let's visualize the number of rides by rider type
all trips v2 %>%
 mutate(weekday = wday(started at, label = TRUE)) %>%
 group by(member casual, weekday) %>%
 summarise(number_of_rides = n()
```

```
,average duration = mean(ride length)) %>%
 arrange(member_casual, weekday) %>%
 ggplot(aes(x = weekday, y = number of rides, fill = member casual)) +
 geom col(position = "dodge")
# Let's create a visualization for average duration
all trips v2 %>%

 group_by(member_casual, weekday) %>%
 summarise(number of rides = n()
      ,average_duration = mean(ride_length)) %>%
 arrange(member_casual, weekday) %>%
 ggplot(aes(x = weekday, y = average duration, fill = member casual)) +
 geom_col(position = "dodge")
# STEP 5: EXPORT SUMMARY FILE FOR FURTHER ANALYSIS
# Create a csv file that we will visualize in Excel, Tableau, or my presentation software
# N.B.: This file location is for a Mac. If you are working on a PC, change the file location
accordingly (most likely "C:\Users\YOUR USERNAME\Desktop\...") to export the data. You can
